Grand Canyon Geology

If a stream initially develops on younger flat strata made of soft material and then cuts downward into the underlying deformed strata while maintaining the course developed in the younger strata, it is referred to as a superposed stream, because the stream pattern was superposed on the underlying rocks. Rainier lahars need to know what the warnings mean and roughly how much time they have between receiving a warning and being in actual danger.

Geologic units in Oregon (state in United States)

As plates converge, one plate may move under the other causing earthquakes, forming volcanoes, or creating deep ocean trenches. A few —such as those off the Mediterranean coast of France and at Porcupine Bank, off the western coast of Ireland—do not have a sharply defined break in slope but rather maintain a generally convex shape to the seafloor.

Continental shelf

A neap tide is the lowest level of high tide; a tide that occurs when the difference between high and low tide is least. Applications of stable water and carbon isotopes in watershed research: Weathering, carbon cycling, and water balances.

Lakes and Reservoirs

Also includes minor rhyolite and dacite flows and domes. This indicated an overall slower rate of depletion in the leeward side compare to the windward side of the Cascades Mountains. The Bonnet Carrie Spillway west of New Orleans is such a floodway.
