The Rocks

The majority of terebratulid species possess a short pedicle by which they are tightly fixed to the substratum. The characteristics and interrelationships of the different facies are explained by two sedimentation models: progradational facies existed contemporaneously during phases of active sediment supply whereas the transgressive facies existed contemporaneously during periods of diminished or absent detrital influx. Respondents experienced more frequent symptoms of psychological distress during and within 30 days of the emergency than 90 days later.
